Accepted manuscripts are the articles in press that have been peer reviewed and accepted for publication by the Editorial Board of the Vojnosanitetski Pregled. They have not yet been copy edited and/or formatted in the publication house style, and the text could still be changed before final publication.

Although accepted manuscripts do not yet have all bibliographic details available, they can already be cited using the year of online publication and the DOI, as follows: article title, the author(s), publication (year), the DOI.

MCA – middle cerebral artery
Abstract

Introduction. Distal anterior cerebral artery (DACA) aneurysms, also known as pericallosal aneurysms are rare, while aneurysms in mirror position are extremely rare. These aneurysms have high tendency for rupture (PHASES score is always >4). In more than a half of the patients with the DACA aneurysm rupture, imaging reveals intracerebral hematoma (ICH), which is a predictor of poor outcome. Case report. 49-year-old female patient was treated endovascularly in other institution, due to middle cerebral artery aneurysm (ACM) rupture, when the two small bilateral aneurysms at the distal segments of ACA were revealed, left one measuring 4.5mm and the right one measuring 6mm in size, with the aneurysmal neck width of 3mm and 4mm, respectively. The decision was made by the interventional neuroradiologist only to treat the bleeding ACM aneurysm immediately. The patient was referred to our department six months later, and it was decided to perform microsurgical occlusion of the remaining DACA aneurysms. Unilateral interhemispheric approach was chosen to reach the distal ACAs. and aneurysms at pericallosal-callosomarginal junction were clipped and excluded from the circulation completely. Conclusion: Management of DACA aneurysms is a surgical challenge, even for experienced neurosurgeons. It is controversial whether these should be surgically clipped or coiled endovascularly, especially in the cases like this one, when a same-stage, endovascular coiling might look like a perfect approach. Surgical treatment should be prompt due to their tendency to early rupture. Careful evaluation for multiplicity is mandatory.

Keywords: aneurysm, anterior cerebral artery, mirror positions, endovascular, microsurgery.

Apstrakt

Uvod. Aneurizme distalnog segmenta prednje moždane arterije (ACA), takođe poznate kao perikalozne arterije su retke, dok su bilateralne aneurizme u identičnoj poziciji ekstremno retke. Ove aneurizme imaju veliku tendenciju ka rupturi (PHASES skor je uvek >4). U više od polovine pacijenata sa rupturom distalne ACA aneurizme formira se intracerebralni hematom (ICH), koji je prediktor lošeg ishoda lečenja. Prikaz bolesnika. Pacijentkinja stara 49 godina je prethodno u drugoj ustanovi lečena endovaskularnom procedurom, zbog rupture aneurizme na srednjemoždanoj arteriji (ACM), kada su dijagnostikovane i dve male simetrične aneurizme na distalnim ACA obostrano, leva dimenzija 4,5mm, a desna 6mm, dok su širine vrata bile 3mm i 4mm. Tada je interventni radiolog doneo odluku da tretira samo krvareću aneurizmu na ACM. Pacijentkinja je upućena u našu ustanovu 6 meseci kasnije, i doneta je odluka da se sprovede mikrohirurško lečenje aneurizmi na distalnim ACA. Uz pomoć unilateralnog interhemisferičnog pristupa i mikrohirurške tehnike su obe simetrične aneurizme na kalozo-kalozomarginalnom spoju isključene iz cirkulacije. Zaključak. Lečenje distalnih ACA aneurizmi je hirurški izazov, čak i za iskusne neurohirurge. I dalje postoji kontraverza u vezi izbora modaliteta lečenja, mikrohiruršija ili endovaskularna procedura, pogotovu u slučajevima kada se koiling u istom aktu sa udruženim aneurizmama čini kao odličan izbor. Mikrohirurško lečenje se ne treba odlagati...
zbog tendencije ka ranoj rupturi ovih aneurizmi. Obavezno je i proveriti postojanje udruženih aneurizmi.

**Ključne reči:** bilateralne aneurizme, prednja moždana aretrija, endovaskularna procedura, mikrohirurščija.

**Introduction**

Distal anterior cerebral artery (DACA) aneurysms, also known as pericallosal aneurysms are rare, and account for approximately 2-9% of all ruptured intracranial aneurysms [1-4]. Studies have previously associated these aneurysms with multiple intracranial aneurysms disease, with multiple aneurysms presence in 55% of cases [4-6]. Several smaller series of DACA aneurysms indicated the frequency of bilateral aneurysms in 10-20% of cases [1, 7], while mirror positioned DACA aneurysms are extremely rare [8-10]. DACA aneurysms are frequently associated with congenital anomalies and anatomic variations of the DACA [8], although, there are reports of patients with DACA mirror aneurysms without any other vascular variation [9].

Typically, DACA aneurysms are small in size, with a wide neck, and with branches originating from the neck or fundus of the aneurysm [11]. The pericallosal-callosomarginal bifurcation is the most common location of DACA aneurysms [12, 13]. These aneurysms have high tendency for rupture (PHASES score is always >4) [6, 14, 15]. In the most of the cases (67-90%) of the ruptures, DACA aneurysms were less than 7 mm in diameter [6, 16]. In more than a half of the patients with the DACA aneurysm rupture, imaging reveals intracerebral hematoma (ICH), which is much more frequent then in other ruptured aneurysms (53-73% versus 26%) [16, 17]. Treatment options available include endovascular coiling, surgical clipping or by-pass surgery, which is the treatment of choice only in complex cases [4, 17-20].

We present a case of surgically treated unruptured mirror aneurysms of the DACAs, accidentally seen during previous endovascular treatment after ACM aneurysm rupture.

**Case report**

Six months before admission to our department, 49-year-old female patient was treated endovascularly, in other institution, due to anterior cerebral artery aneurysm (ACM) rupture manifested with subarachnoid hemorrhage (SAH). Digital subtraction angiography (DSA), performed in the course, confirmed the existence of bilobular right ACM aneurysm, and also revealed two small bilateral aneurysms at the distal segments of ACA, left one measuring 4,5mm and the right one measuring 6mm in size, with the aneurysmal neck width of 3mm and 4mm, respectively, without other vascular malformations revealed. (Figure 1).

The decision was made by the interventional neuroradiologist only to treat the bleeding ACM aneurysm immediately, while both ACA aneurysms were deemed unsuitable for endovascular treatment at the given moment. The post-procedural period passed without any complications. Follow-up MSCT angiography confirmed the existence of bilateral
aneurysms on DACA segments one more time, as well as complete occlusion of the right MCA aneurysm (*Figure 2*).

The patient was referred to our department six months later, and it was decided to perform microsurgical occlusion of the remaining ACA aneurysms. Unilateral interhemispheric approach was chosen to reach the distal ACAs. Retraction brain injury was prevented by evacuation of about 15ml of cerebrospinal fluid by lumbar puncture preoperatively. Proximal pericallosal ACA segments were identified and then bilateral aneurysms at pericallosal-callosomarginal junction. Both aneurysms were clipped and excluded from the circulation completely, also major draining veins are preserved.

Postoperative course went well and the patient was discharged from our department on the seventh postoperative day without any neurological deficit. Two months after the surgery, follow-up MSCT angiography revealed that all three aneurysms were completely excluded from circulation.

**Discussion**

Management of DACA aneurysms is a surgical challenge, therefore it is controversial whether these should be surgically clipped or coiled endovascularly, especially in the cases when these are incidentally seen during the endovascular procedure for other aneurysm embolization, when a same-stage, endovascular coiling might look like a perfect approach to occlude mirror DACA aneurysms.

Although endovascular coiling is less invasive, and considered less harmful for the patient, it is associated with significantly higher periprocedural rupture [18] and procedure related morbidity [21] than other circle of Willis aneurysms. Surgical clipping results, on the other hand, are same or slightly better than for aneurysms at other locations [16].

DACA aneurysms are still treated with microsurgical clipping more often than endovascular coiling due to their distal location and morphologic features, nevertheless surgical clipping remains demanding. Moreover, because of their rare occurrence, neurosurgeons often have the lack of experience in surgical treatment of these aneurysms [5, 7, 11, 16].

Non-experienced surgeons are avoiding to operate due to location of the DACA aneurysms in the narrow interhemispheric space [22], difficulties in establishing proximal control, and the high frequency of wide-necked and sclerotic aneurysms in this location, in particular those involving the origin of the branching arteries [4, 21].

Regarding the aneurysm size, only a few cases of a large and giant DACA aneurysms have been reported [5, 6, 14]. Average diameter at the moment of the rupture according to Gherasim et al. was 5.5mm, versus 9mm compared with all other intracranial aneurysms which can be explained due to the lack of resistant arachnoid membranes at the level of the pericallosal cisterns [19]. In our case aneurysms at the distal segments of ACA, were measuring 4.5mm on the left, and the right one measuring 6mm in size, therefore demanding prompt surgical treatment.
According to meta-analysis of Ondra et al. aneurysm recurrence occurred in 3% after surgery and in 19.1% after endovascular treatment, although, in this series, there were no significant differences in procedure-related morbidity and mortality [23]. The most important factor affecting the mortality and morbidity is the presence of associated aneurysms [5]. One stage surgery with unilateral craniotomy is suggested for bilateral DACA and mirror aneurysms, which is relatively straightforward due to their proximity [4], but also in cases when DACA aneurysms were associated with aneurysms at different location to reduce the morbidity and mortality [24, 25].

Initial haemorrhagic event related to DACA aneurysm rupture in more than a half of patients is ICH, which is considered to increase the risk of poor (lethal) outcome [26, 27]. The high incidence of ICHs, higher than for aneurysms elsewhere, is obviously related to the narrow pericallosal cistern and the dense attachments to the adjacent brain surface [26, 28]. IVH is a little less frequent, appearing in 25−30% of the patients [28]. This fact is also supporting our decision to proceed with surgical clipping, due to the possibility of immediate management of the intraoperative/intraprocedural rupture. Also, the risk of ischemic event is better handled, due to better intraoperative overview and handling of the small branches originating from the aneurysm dome.

Bearing in mind the tendency for rupture regardless of small aneurysm size, high incidence of intracerebral hemorrhage, and a relatively high risk of aneurysm recurrence after endovascular treatment at this location [11, 16, 23, 26], we believe that both interventional radiologists and our decision for subsequent early microsurgical treatment was justified.

**Conclusion**

Successful surgical management of DACA aneurysms mostly depends on understanding of their unique microsurgical anatomy and the surgeon's experience, as well as careful preparation and examination of the patient.

- All patients with DACA aneurysms should be carefully evaluated with DSA or MSCT angiography for the presence of additional aneurysms due to the tendency for multiplicity [5, 26]

- Even the DACA aneurysms revealed during the endovascular procedure, should be referred to surgical treatment as soon as possible [21, 26] (not treated in the same procedure).

- They should be aggressively treated even if they are very small because of their tendency to early rupture [15]

Sufficient brain relaxation, accurate localization of the aneurysm, early identification of the proximal ACA segment, and preservation of the major draining veins, remain necessary for a safe surgery.
